LEONARDO DA VINCI

Leonardo Da Vinci

(April 15, 1452 - May 2, 1519)

*“Iron rusts from disuse; stagnant water
loses its purity and in cold weather becomes frozen;
even so does inaction sap the vigor of the mind.”*

Leonardo

Leonardo da Vinci was born April 15, 1452 in Vinci, Italy. Da Vinci was an artist, scientist, mathematician, engineer, inventor, anatomist, sculptor, architect, botanist, musician and writer. He has often been described as a perfect example of a Renaissance man, a man whose unquenchable curiosity was equaled only by his powers of invention and observation. Da Vinci is widely considered to be one of the greatest painters of all time and perhaps the most diversely talented person to have ever lived.

At an early age, Da Vinci's talent for drawing became evident, and his father apprenticed his young son to a noted period artist, Andrea del Verrocchio. Through the coming years, the young Leonardo learned much from his mentor and at the age of thirty, Da Vinci left Florence and settled in Milan and established a workshop. During the following years, he earned his living painting commissioned pieces. He soon came to the conclusion that it was not possible for him to earn steady income doing this and began his search for employment. He began by writing a letter to the Duchy of Milan, Duke Ludovico Sforza, known by the nickname, the Moor. In this correspondence, Da Vinci stated that he had studied machines of war and had come up with improvements that would

LEONARDO DA VINCI

strengthen the Moor's position in battles. The letter hinted at inventions that included portable lightweight bridges and improved designs for bombards, mortars, catapults, covered assault vehicles and weapons. The Moor eventually became Da Vinci's patron and kept him busy with everything from designing a heating system to painting portraits, to overseeing production of cannons and even decorating the vaulted ceilings in his castle.

It was during this time that Da Vinci began writing and drawing in his journals. These volumes became repositories of the outflow of Leonardo's gifted mind. He was a voracious student of the universe and his observations led to magnificent plans and concepts. Da Vinci's notebooks consist of more than 20,000 sketches, copious notes and detailed drawings. Some of his conceptual designs led to the greatest inventions of his day, while others came to fruition hundreds of years after his initial concepts were penned, simply because the machinery needed to build and power them were not yet invented. Leonardo's notebooks clearly illustrate his genius of not only improving upon existing inventions, but also conceiving a myriad of new ideas and designs.

Ultimately, the Moor was captured by the French and Da Vinci left Milan in search of a new patron. He traveled through Italy for more than a decade, working for several Dukes and rulers, including Cesare Borgia, a General intent on conquering central Italy. Leonardo traveled with Borgia as a military engineer, designing weapons, fortresses and artillery, but became disillusioned and quickly left his service with the General. It seems that despite Da Vinci's design for artillery and weaponry, he was actually a pacifist and detested war and its destruction.

LEONARDO DA VINCI

Da Vinci later took positions with King Louis XII and Pope Leo X and ultimately with the King of France, Francis I. It was the King who offered Da Vinci the title, Premier Painter and Engineer and Architect of the King. Francis I valued Da Vinci's great mind and his sole function was to engage in conversations about Renaissance culture and art with the benevolent royal.

ARTISTIC MASTERPIECES OF LEONARDO DA VINCI

It is important to remember that Da Vinci is not only a great inventor, but is considered to be one of the most acclaimed artists to ever have lived, creating such masterpieces as The Last Supper (c.1498) and the Mona Lisa (c.1503). Leonardo's drawing of the Vitruvian Man is also regarded as a masterpiece. Unfortunately, only a small number of Da Vinci's paintings have survived. Leonardo experimented with new techniques, most of which did not yield

Vitruvian Man (circa 1487)

long-lasting results. The master painter was also somewhat of a perfectionist with fastidious attention to detail. It is believed that when painting the Mona Lisa, the artist spent ten years perfecting the lips of this masterpiece.

The Mona Lisa (circa 1503)

The Last Supper (circa 1498)

LEONARDO DA VINCI

Da Vinci's Notebooks

Da Vinci's notebooks are now more than 500 years old. Most of them are not bound the way a typical book would be today, but rather comprised of loose sheets of paper gathered into collections and wrapped with fabric. Paper was scarce in Da Vinci's time, so he used every available space in a page for drawings, observations, even recipes and shopping lists, making them somewhat difficult to interpret. Adding to the difficulty in deciphering his works was the fact that Da Vinci's scripted notes were written backwards, or in a mirror image, and read from right to left. His reason for this remains a mystery, but it is thought that Leonardo's theories sometimes went against church teachings and his secret writing could have been a way to avoid scrutiny. Da Vinci also might have feared that someone would steal his designs and publish them under their own name. Ironically, Da Vinci addressed an imaginary readership in the margins of his notebooks urging the reader to make sure his work was printed into a proper book. It is presumed that he meant for the notebooks to be published after his death.

LEONARDO DA VINCI

Da Vinci's Notebooks

Several common themes recur in the now fragile notebooks: nature, technology (including gears, cogwheels, screws and pulleys), aviation and vision, to name a few. Upon the death of Leonardo Da Vinci, the notebooks were given to his long-time friend, Count Francesco Melzi. After his death, Melzi's heirs did not fully comprehend the value of the information and the manuscripts were dispersed. They placed the notebooks in an attic where they were viewed by guests who sometimes took pages with them as souvenirs. In a few years Melzi's family lost all the manuscripts and soon pages were scattered across Europe.

Da Vinci's notebook extracts were published in 1883 and about half of them have not yet resurfaced so far. It is easy to imagine that had the notebooks been published earlier, the history of science might have been completely changed.

In his drawings, Leonardo strived for *saper vedere* or "knowing how to see." Da Vinci's illustrations are unparalleled and some experts believe that no one has since been better.

LEONARDO DA VINCI

❧ SUBMARINE ❧

Codex Atlanticus, folio 881r

The submarine has always been thought of as one of Leonardo Da Vinci's inventions, but until the discoveries made by the Leonardo3 studies centre, no one had ever found the definitive drawings and attempted to build a model. Da Vinci did a lot of work around naval weapons and battle techniques up until the time he arrived in Milan at the court of Ludovico Sforza in 1582. He also travelled to Venice and often found himself requested for advanced and top secret naval weapons. His manuscripts show that he had studied the naval engineering manuscripts of his time and many projects found in his designs were copied from other engineers. However, in addition to studying existing techniques, Da Vinci looked for other solutions and tried both to improve the techniques employed at the time and to invent new and even more powerful weapons. The first clue to the Submarine can be found on Manuscript B on folio 11r, where Da Vinci drew a closed shape with an opening on top and explained in a few lines that the air inside this secret weapon must be managed correctly to prevent it from sinking. He also alludes to secret weapons but leaves no trace of them.

Codex Atlanticus, folio 159r

LEONARDO DA VINCI

The idea of a shell which sailed under water had already been thought of by previous engineers, such as Taccola and Francesco di Giorgio. Da Vinci was certainly inspired by his colleagues, but he developed the idea, putting more serious thought into whether or not it was feasible. The weapons that Da Vinci wanted to put inside the submarine are described in Manuscript B and in other pages of the Codex Atlanticus. They refer to screws and mechanical springs capable of drilling into the planking of enemy ships and disembowelling them.

Until studies carried out by Leonardo3 in 2011, the submarine had never been reconstructed because the drawings and notes were never considered clear or complete. There is a very damaged and moulding sheet, folio 188r of the Codex Atlanticus, from which almost all the drawings have disappeared. A few items such as a fin, oars and other strange mechanisms are just recognisable. The sheet is blue and with the passage of time the ink has become almost invisible. Using digital processing it was possible to bring the hidden drawings back to life; around 40 different items and some writing was uncovered in this way.

There isn't a completed project, but a series of indications and mechanisms which, when put together, bring to light one of Da Vinci's most deadly secret projects: the Mechanical Submarine. All of the drawings uncovered on folio 881r are underwater mechanisms and experiments. Da Vinci himself said that because it was a lethal weapon it must not fall into enemy hands, and this may be another reason why, instead of drawing the final project, he drew it disassembled and in a way that makes it difficult to understand. After studying the drawings at length and analysing the other drawings throughout all the codices, it was possible to reconstruct in the Leonardo3 laboratories, first in 3D and then physically, the real Leonardo Da Vinci Submarine for the first time.

LEONARDO DA VINCI

A boat with sails has a part which is submerged in the water and invisible to enemies. The pilot uses a passage to get into the lower part undercover: the Mechanical Submarine. A pulley and rope system lowers the submarine which can unhook itself underwater and proceed invisibly towards the enemy. The submarine has two air chambers which can be used for steering and also for air needed by the pilot, who has a mouthpiece. Steering underwater is done by means of a mechanical system. The pilot's feet turn a mechanical motor which transforms the pedalling motion into the mechanical movement of two fins to the rear.

The submarine is propelled forward by the fins as if it were a mechanical fish, and a system of two rudders steered with the arms maneuvers the saboteur underneath an enemy ship. Once there, the submarine can use the spring and screw weapons to pierce the keel of the ship to sink it. Da Vinci considered the system of the secret mechanical submarine a lethal weapon and incredibly dangerous; it is almost impossible for the enemy to detect it and it can cause a great deal of damage to an entire fleet.

LEONARDO DA VINCI

How To Operate The Submarine

1

LEONARDO DA VINCI

The scientific genius of Leonardo Da Vinci is brought to life through articulated models offered by Edu-Science. The inventions that inspired these snap-together replicas are taken from the pages of Da Vinci's priceless and awe-inspiring notebooks.

Edu-Science Da Vinci Series Kits

DV001

Mechanical Drum

Leonardo da Vinci's mechanical drum was designed as a cart equipped with an amply sized drum. When pulled by its handle, the gears turn the two lateral drums, which are fitted with pegs. The pegs move a total of ten drumsticks that cause them to beat the large drum.

Aerial Screw

The Aerial Screw design is a precursor of the modern day helicopter. The drawing of Da Vinci's concept illustrated the compression of air that was intended to lift the upper part (propeller or screw) the device off the ground.

DV002

LEONARDO DA VINCI

Swing Bridge

This arched bridge built on a river turns on a central pivot to let boats pass. It is counterbalanced by a case of stones and turns by winches set on the river bank.

DV003

Printing Press

Leonardo da Vinci studied the Guttenberg printing press and finely-tuned it for greater efficiency. In his design, he used a hand press with an automatic system that moved the type-saddle forward and back along a tilted surface, making printing faster and easier.

DV005

DV006

Multi-barreled Canon

The 10-barreled gun carriage was developed to give the traditional canon additional firepower and was a potentially effective weapon against a line of advancing troops.

Armored Car

A precursor to the modern-day tank, the armored car was capable of multi-directional movement and was equipped with cannons arranged in a 360-degree firing range around its circumference.

DV007

LEONARDO DA VINCI

DV008

Paddleboat

In Da Vinci's time, nautical expedition was the most expedient method of communicating with the world and his design for a boat with large wheel-shaped paddles that would propel it through water offered a faster and easier method of water transportation.

Self-Propelled Cart

Da Vinci's self-propelled cart was the first to be capable of moving without being pushed or pulled manually.

But it is not a car! It is a kind of robot, designed to take by self-movement a puppet on the stage of a theater. And probably with a programmed path.

DV009

Catapult

Improvements were made to the age-old military launching device called a catapult.

The new design employed a hand-crank that caused tension on the throw arm.

The spring design produced a large amount of energy in order to propel stone projectiles or incendiary materials over great distances.

DV010

Bombard

This improved cannon was designed to include projectiles that contained a quantity of mini gunpowder shots packed into petal-shaped iron pieces that formed a ball.

The device exploded into fragments that had greater range and impact than a single cannonball.

DV011

LEONARDO DA VINCI

DV012

Mechanical Butterfly

Leonardo da Vinci himself advised where one can admire these incredible flying insects:

To see four-winged flying, look near ditches and you will see dragonflies.

It is extremely difficult to create a mechanical replica of the natural

movement of an animal. The beating of the dragonfly's four wings is particularly complex and Da Vinci was well aware of how difficult it would be to create this machine, he himself described it in great detail. It is not simply wings beating up and down; it's a jointed motion. Whilst beating down the wings are "flat" in order to push as much air as possible, whereas when they are raised, they are angled so that they create less resistance.

Giant Crossbow

The structure of the crossbow is relatively simply. It has a rigid wooden body, on which the stock and a bow are mounted. Compared to a traditional bow, the crossbow is very compact; the bow of more modern crossbows is made from metal, is not very long, but very thick. This is why the bow of the crossbow is less flexible than that of a traditional bow, and the string is much tauter. The distinguishing feature of the crossbow

DV013

is a launching mechanism similar to a trigger on modern weapons. The project follows a rather typical pattern, seen in Leonardo da Vinci's other projects – making an existing weapon more powerful by making it bigger and in some cases making it multiple launch (as in the cases of the Multiple Sling, the Armoured Tank, the Multiple Bombard and other drawings).

LEONARDO DA VINCI

DV015

Submarine

Leonardo da Vinci himself said that because it was a lethal weapon it must not fall into enemy hands, and this may be another reason why, instead of drawing the final project, he drew it disassembled and in a way that makes it difficult to understand. A boat with sails has a part which is submerged in the

water and invisible to enemies. The pilot uses a passage to get into the lower part undercover: the Mechanical Submarine. A pulley and rope system lowers the submarine which can unhook itself underwater and proceed invisibly towards the enemy. The submarine has two air chambers which can be used for steering and also for air needed by the pilot, who has a mouthpiece. Steering underwater is done by means of a mechanical system.

Great Kite

The genius Da Vinci drew inspiration for his work from his direct observation of the flight of a bird. Da Vinci described its dimensions, the materials with which it is to be built, its shape and how it works; the whole notebook revolves precisely around the construction and use of the machine. Da Vinci also imparted some

“flying lessons” on how the pilot should operate the machine. The piloting must have been complex. He would use his hands and feet to activate ropes and could rotate, move and open and close the wings with his own movements. Da Vinci’s design is not drawn in its entirety. We must therefore reconstruct the indispensable parts. These include: the canvas to cover the wings, some articulations and pulleys, and the tail, which Da Vinci knew was indispensable for controlling the machine.

DV016

LEONARDO DA VINCI

DV017

Multiple Sling

Leonardo da Vinci's idea was to build a very powerful machine which could throw eight large projectiles at the same time.

He positioned eight long arms in a circle around a central pin, each of which had a sling capable of throwing a projectile attached to it.

This kind of project, where weapons were developed to hurl multiple

projectiles to be more powerful, was common in Da Vinci's time, because doing this meant creating more powerful weapons, simply by increasing their number and power, without the need to develop new building techniques and using familiar materials. They were therefore potentially attractive weapons because they were powerful, but they were also relatively inexpensive.

Ship's Cannon with Shield

The prow of the ship and the cannon are protected by a wooden shield. Leonardo da Vinci studied this subject closely, identified the weak points and invented his own version with many more functions. First, he concentrated on the structure of the vessel which needed to be reinforced and keep the cannon firmly in the middle. The shield, which previous engineers had shown as being immobile and almost temporary, in Da Vinci's drawing was split in two and became part of the structure and mobile. A system of ropes and pulleys keeps the shields raised to protect the ship. Once the winches are locked, the weight of the shields themselves causes them to rotate outwards to uncover the cannon which can then fire.
